## 1.0 PROJECT SUMMARY

## **1.1 INTRODUCTION**

The SLRC Bypass Project is part of the SLRC Storage Replacement Project. This project is intended to replace the water storage provided by the Ivanhoe and Silver Lake Reservoirs and makes possible the preservation of these two bodies of water. The SLRC Bypass Project consists of approximately 4,600 linear feet of 66-inch diameter welded steel pipe, a regulator station, and a pressure relief station. The project, as originally proposed in the Environmental Impact Report for the SLRC Storage Replacement Project, was to have consisted of a large underground tunnel beneath West Silver Lake Drive. In an effort to minimize the construction impacts on the Silver Lake community, the LADWP is pursuing an in-reservoir approach which consists of open trench construction along a portion of West Silver Lake Drive and along the bottom of Silver Lake Reservoir.

This air monitoring project was designed to measure the concentrations of particulate matter with a mean aerodynamic diameter of 10 microns or less ( $PM_{10}$ ) in the vicinity of the Silver Lake Reservoir at four distinct locations surrounding the reservoir in the absence of construction activities.

Baseline sampling occurred at all four locations for two consecutive days (March 11<sup>th</sup> and 12<sup>th</sup>, 2015). The following sections provide the details of the sampling that took place and provides the results attained from this baseline monitoring project.

## **1.2 PARAMETERS**

Particulate concentration data has been obtained through the use of four semi-portable, programmable, mass-flow controlled  $PM_{10}$  samplers. The sampler of choice for this project is the BGI PQ167 (U.S. EPA Reference Method: RFPS-1298-124). The PQ167 sampler is highly reliable and easy to calibrate. The PQ167 sampler continuously monitors flow rate and adjusts the pump speed to maintain a consistent flow rate of 16.7 liters per minute (lpm). This flow rate is critical for the separation of  $PM_{10}$  from particulates of greater size. The PQ167 stores all of the valid sampling run parameters and calculates the total volume for each sampling event.

## **1.3 SITE LOCATIONS**

The following are actual sampling locations for the above mentioned monitors during this baseline sampling project (See Figure 1-1):

Baseline Monitoring Site #1: Latitude: 34° 06.243' Longitude: 118° 15.894' Baseline Monitoring Site #2: Latitude: 34° 05.928' Longitude: 118° 15.731' Baseline Monitoring Site #3: Latitude: 34° 05.559' Longitude: 118° 15.854'

Baseline Monitoring Site #4:Latitude:34° 05.932'Longitude:118° 15.975'

These locations were chosen based on the following priorities:

- Representativeness of background concentrations in the vicinity of the Silver Lake and Ivanhoe Reservoirs; and
- Security.

#### SCS TRACER ENVIRONMENTAL

### FIGURE 1-1: FIELD SAMPLING LOCATIONS

## **1.4 ORGANIZATION**

The project is organized as described in the following paragraphs. The description provides individual personnel assigned to the project as well as their responsibilities.

Paul Schafer serves as the overall Project Manager and is responsible for all aspects of the program. This includes oversight of operation, maintenance and data reporting activities as well as correspondence with ESA and the Los Angeles Department of Water and Power (LADWP) personnel. In this capacity he is responsible for direct oversight of the field and data technicians. He is also responsible for facilitating repairs of instruments as well as QA/QC compliance on the program.

Tyler Thomason provided field technician support to the program. Tyler was responsible for onsite operations to include site visits, QA/QC checks and collection of sample media.

Tyler Thomason provides lab and database support to the program. He is responsible for analytical procedures as well as updating the database.

## 2.0 APPLICABLE DATA CAPTURE SUMMARIES

## 2.1 INTRODUCTION

This section contains various applicable data capture summary tables.

## 2.2 INVALID DATA

This section contains a table listing all the invalid samples for this project period along with the reason for the invalidation.

### TABLE 2-1: INVALID DATA FOR PM10

Sampling Day	Sampling Location	Reason

Total Invalid Samples: 0

There were no invalid samples during this reporting period.

## 2.3 PM<sub>10</sub> DATA

This section contains the table of sampling parameters (Table 2-2) as well as the table of time averaged  $PM_{10}$  concentrations (Table 2-3). Concentration data is reported in micrograms per cubic meter ( $\mu g/m^3$ ).

#### TABLE 2-2: SAMPLE PARAMETERS

Date	Sample ID	Sampling Site	Start Time	Stop Time	Total Time (min)	Sample Volume (m^3)

## **TABLE 2-3: MEASURED TIME AVERAGED PM-10 CONCENTRATIONS**

## 3.0 QUALITY ASSURANCE AND QUALITY CONTROL DATA SUMMARIES

## 3.1 CALIBRATION FORMS AND SITE LOGS

Site Logs and calibration forms relative to the operations performed during this monitoring period are included in Appendix A and B respectively. The information these records contain include:

- Results of Calibrations;
- Adherence to all applicable protocols; and
- Diligence of operators to assure the quality of the data generated.

## 4.0 **RESULTS AND CONCLUSIONS**

## 4.1 INTERPRETATION OF RESULTS

When interpreting the results of the baseline monitoring data the following relationships are investigated:

- 1. Relative difference to established benchmarks (the California State Standard for 24-hr  $PM_{10}$  concentration if 50  $\mu$ g/m<sup>3</sup>),
- 2. Spatial Differences: What are the differences in concentration relative to sampling location, and
- 3. Temporal Differences: What are the differences in concentration relative to the time of the sampling?

The following section will provide some commentary on the data collected relative to these relationships.

#### 4.2 CONCLUSIONS

- 1. Many of the baseline samples exceeded the CA State benchmark of  $50 \ \mu g/m^3$ . In fact, 6 of the 8 samples taken during this project exceeded this benchmark. The highest concentration measured was at Site #1 on March 21, 2015 and resulted in a concentration of 185% (92.3  $\mu g/m^3$ ) of the benchmark. However, it should be noted that the samples taken where 8-hr time averaged samples and concentrations would likely change with a 24-hr sampling period. The project was designed to measure concentrations during the period of the day that construction activities are likely to occur for comparison purposes to monitoring during construction activities.
- 2. Spatial differences in concentration were fairly significant. On both sampling days, Sites 1 and 3 had significantly higher concentrations than Sites 2 and 4. This indicates that Sites 1 and 3 were impacted by a local source(s) to a greater degree than Sites 2 and 4 during the period sampled. Sites 2 and 4 appear to be indicative of regional background levels while Sites 1 and 3 appear to be influenced to a greater degree by more local particulate sources.
- 3. Temporal differences in concentration were also fairly significant during these two sampling days. Samples taken on March 11<sup>th</sup> appeared to have a significantly higher regional background relative to the samples taken on March 12<sup>th</sup>. Meteorological variables such as a lower inversion layer on the 11<sup>th</sup> likely contributed to the difference in regional background levels on the two days.

#### 4.3 DATA LIMITATIONS

There are several limitations associated with this sampling project. The major limitations are as follows:

- The results correspond to one particular period of time. These results would not necessarily be reproducible at another given period of time.
- Meteorological parameters significantly influence pollutant concentrations. These variables need to be considered.
- The data obtained in this sampling project are time averaged concentrations. Different averaging periods may lead to varying results.
- The project area is urban and multiple sources exist at varying times which are significant distances apart. The proximity of a sampler to a specific source greatly influences the impacts of that source on the sample. The individual impacts of each source cannot be defined.
- Some sources of particulate generation may be directly upwind from a given sampling site while other sources may not be given a prevailing wind direction. Also, although we are able to determine prevailing wind direction, wind direction is variable throughout a day.
